

The following is a complete listing of all claims in the application, with an indication of the status of each:

Listing of claims:

1-3. (Cancelled)

4. (Previously presented) A Japanese letter input device for a portable terminal comprising:

a direction designation unit having a plurality of direction designation positions uniformly spaced apart in a circle with a center position and a predetermined radius, the direction designation unit including a pointer capable of being moved radially in a two dimensional plane from a reference position located at the center position of the circle to a first direction designation position and then circumferentially to a second direction designation position, and then returned to the reference position, the direction designation unit detecting the first direction designation position, which the pointer is first radially moved to, and the second direction designation position, which the pointer is located at after being moved circumferentially and before being returned to the reference position, and outputting position data of the detected direction designation positions;

a data processing unit for generating letter codes from the position data outputted from the direction designation unit by using a memory means with a letter set stored therein; and

a display unit displaying the letter codes generated at the data processing unit.

5. (Original) The Japanese letter input device for a portable terminal according to claim 4, which further comprises a buffer for temporarily storing input data of the direction designation unit.

6. (Original) The Japanese letter input device for a portable terminal according to claim 4, in which a plurality of letter sets are stored, and which further comprises a means for selecting each of the letter sets.

7. (Original) The Japanese letter input device for a portable terminal according to claim 6, wherein one of the letter sets is in the form of an M-column N-row matrix array obtained by

arranging kana letters in the 50-letter set in a matrix array of columns and rows, the columns each consisting of letters assigned by the same consonant, the rows consisting of letters of the same level, and symbols including the consonant mark and the p-sound mark, direction designation positions being each allotted to each row of the letter set.

8. (Original) The Japanese letter input device for a portable terminal according to claim 6, wherein one of the letter sets is obtained by arranging romaji alphabet letters, numerals and symbols in M columns and N rows.

9. (Previously presented) The Japanese letter input device for a portable terminal according to claim 4, wherein the data processing unit selects a row of the letter set corresponding to the first direction designation position represented by the position data outputted from the direction designation unit.

10. (Original) The Japanese letter input device for a portable terminal according to claim 9, wherein the data processing unit detects, upon reception of the position data representing the second direction designation position from the direction designation unit, an interval of circumferential movement of the pointer from the difference between this position data and the previously received position-data representing the first direction designation position, selects a row of the letter set, and outputs, upon reception of a determination signal, a code of a particular letter or symbol in the letter set by combining the selected column and row of the letter set.

11. (Original) The Japanese letter input device for a portable terminal according to claim 10, wherein the direction designation unit continuously outputs position data during movement of the pointer, and the data processing unit causes, upon reception of the position data of the first direction designation position, a code representing a row of the letter set corresponding to the first direction designation position, for instance the first column letter in the same row, to be displayed on the display unit, causes, after determination of the displayed row of the letter set, letters representing columns determined by intervals of movement of the pointer to be

successively displayed on the display unit, and outputs, upon determination of a displayed letter, a signal representing the same displayed letter.

12. (Original) The Japanese letter input device according to claim 4, wherein the data processing unit causes, while the pointer is circumferentially moved in a predetermined direction after starting movement from the reference position and reaching the first direction designation position, causes such row selection mode indication as to cause letters representing rows of the letter set corresponding to relayed direction designating positions to be successively displayed on the display unit, determines, when the pointer is once stopped and then turns to be moved in the reverse direction, a row of the letter set corresponding to the direction designation position, which the pointer is once stopped at, while also deciding that a row selection mode has been set up and causing successive display of letters representing rows corresponding to intervals of movement of the pointer, decides, when the pointer is returned to the reference position, that the prevailing displayed row has been determined, thus outputting a signal of a letter corresponding to the determined column and row.

13. (Original) The Japanese letter input device for a portable terminal according to claim 4, wherein the direction designation unit includes a determining switch for informing, when the first and second direction designation positions and the combination thereof are determined while the pointer is moved, the determination to the data processing unit.

14. (Previously presented) The Japanese letter input device for a portable terminal according to claim 4, wherein the direction designation unit includes a pointer mechanism having a plurality of direction designation positions uniformly spaced apart on two concentric circles, the pointer mechanism detecting each of the direction designation positions stepwise when tilted from a center position in radial direction.

15. (Previously presented) The Japanese letter input unit for a portable terminal according to claim 14, wherein the direction designation unit is switchable between a column input mode and a row input mode in dependence on two different tilting angles, effect column input when tilted

by small angle, effects row input when tilted by large angle, effects column determination when tilted to the large angle during the column selection in the small angle tilted state, effects row selection when tilted to the large angle once again, effects row determination when subsequently returned to the center position, and effects input of a Japanese kana letter by combining the determined column and row.

16. (Original) The Japanese letter input device according to claim 15, wherein the direction designation unit inputs a consonant of the Japanese kana letter set at the time of the column input, and inputs a vowel of the Japanese kana letter set at the time of the row input.

17. (Original) The Japanese letter input device according to claim 15, wherein the direction designation unit inputs letters in a romaji alphabet letter set at the time of the column input, and inputs the orders of the inputted letters at the time of the row input.

18. (Original) The Japanese letter input device for a portable terminal according to claim 4, which further comprises a button or like switch for switching a letter input operation and a cursor operation of the direction designation unit over to each other.

19. (Previously presented) The Japanese letter input device for a portable operation according to claim 18, wherein the direction designation can be switched to set up a cursor movement mode and a display scroll mode in dependence on angles of tilting it when used for the cursor operation, the cursor movement mode being set up by tilting the unit by small angle, the display scroll mode being set up by tilting the unit by a large angle.

20. (Previously presented) The Japanese letter input device for a portable terminal according to claim 19, wherein when the direction designation unit is used for the cursor operation, the extent of movement of cursor is changed according to the tilting angle of the pointer for inputting commands concerning the display operation.

21. (Original) The Japanese letter input device for a portable terminal according to claim 15, wherein the direction designation unit includes an elastic member to let a tilting angle of the pointer be known with a feel of click.

22. (Original) The Japanese letter input device according to claim 21, wherein the direction designation unit has a structure that the user is given a feel of click whenever the pointer being circumferentially moved reaches a direction designation position.

23. (Currently Amended) A Japanese letter input method for inputting letters and symbols in a letter set for use in a Japanese letter input device, comprising the steps of
disposing predetermined letters and symbols in a concentric circle form; and
inputting letters or symbols by designating, in a predetermined sequence, coordinates on the concentric circle form corresponding to the letters and symbols by using a position input device, wherein said position input device is capable of moving from a center of said concentric circle form outward along one of several directions to a point on the circumference of said concentric circle form, and wherein selection of letters or symbols is made using a memory unit.

24. (Cancelled).

25. (Cancelled)

26. (Previously presented) The Japanese letter input method of claim 23, wherein the letter set includes romanji alphabet letters, numerals and symbols.

27. (Previously presented) A Japanese letter input method for inputting letters in a letter set used in a Japanese letter input device, comprising the steps of

i) providing a Japanese letter input device for a portable terminal, wherein said input device comprises

a direction designation unit having a plurality of direction designation positions uniformly spaced apart in a circle with a center position and a predetermined

- radius, the direction designation unit including a pointer;
- ii) moving said pointer radially in a two-dimensional plane from a reference position located at the center position of the circle to a first direction designation position;
 - iii) moving said pointer circumferentially to a second direction designation position;
 - iv) returning said pointer to the reference position;
 - v) detecting said first and second direction designation positions;
 - vi) outputting first and second direction designation position data to a data processing unit by means of a memory means with a letter set stored therein; and
 - vii) displaying letter codes generated at the data processing unit.
28. (Previously presented) The method of claim 27 further comprising temporarily storing input data of the direction unit in a buffer.
29. (Previously presented) The method of claim 27 wherein a plurality of letter sets are stored in said memory means, and a means for selecting each of the letter sets is provided.
30. (Previously presented) The method of claim 29, wherein one of the letter sets is in the form of an M-column N-row matrix array obtained by arranging kana letters in the 50-letter set in a matrix array of columns and rows, the columns each consisting of letters assigned by the same consonant, the rows consisting of letters of the same level, and symbols including the consonant mark and the p-sound mark, direction designation positions being each allotted to each row of the letter set.

31. (Previously presented) The method of claim 29, wherein one of the letter sets is obtained by arranging romaji alphabet letters, numerals and symbols in M columns and N rows.

32. (Previously presented) The method of claim 27, wherein the data processing unit selects a row of the letter set corresponding to the first direction designation position represented by the position data outputted from the direction designation unit.

33. (Previously presented) The method of claim 32, wherein the data processing unit detects, upon reception of the position data representing the second direction designation position from the direction designation unit, an interval of circumferential movement of the pointer from the difference between this position data and the previously received position-data representing the first direction designation position, selects a row of the letter set, and outputs, upon reception of a determination signal, a code of a particular letter or symbol in the letter set by combining the selected column and row of the letter set.

34. (Previously presented) The method of claim 33, wherein the direction designation unit continuously outputs position data during movement of the pointer, and the data processing unit causes, upon reception of the position data of the first direction designation position, a code representing a row of the letter set corresponding to the first direction designation position, for instance the first column letter in the same row, to be displayed on the display unit, causes, after determination of the displayed row of the letter set, letters representing columns determined by intervals of movement of the pointer to be successively displayed on the display unit, and outputs, upon determination of a displayed letter, a signal representing the same displayed letter.

35. (Previously presented) The method of claim 27, wherein the data processing unit causes, while the pointer is circumferentially moved in a predetermined direction after starting movement from the reference position and reaching the first direction designation position, causes such row selection mode indication as to cause letters representing rows of the letter set corresponding to relayed direction designating positions to be successively displayed on the display unit, determines, when the pointer is once stopped and then turns to be moved in the

reverse direction, a row of the letter set corresponding to the direction designation position, which the pointer is once stopped at, while also deciding that a row selection mode has been set up and causing successive display of letters representing rows corresponding to intervals of movement of the pointer, decides, when the pointer is returned to the reference position, that the prevailing displayed row has been determined, thus outputting a signal of a letter corresponding to the determined column and row.

36. (Previously presented) The method of claim 27, wherein the direction designation unit includes a determining switch for informing, when the first and second direction designation positions and the combination thereof are determined while the pointer is moved, the determination to the data processing unit.

37. (Previously presented) The method of claim 27, wherein the direction designation unit includes a pointer mechanism having a plurality of direction designation positions uniformly spaced apart on two concentric circles, the pointer mechanism detecting each of the direction designation positions stepwise when tilted from a center position in radial direction.

38. (Previously presented) The method of claim 37, wherein the direction designation unit is switchable between a column input mode and a row input mode in dependence on two different tilting angles, effect column input when tilted by small angle, effects row input when tilted by large angle, effects column determination when tilted to the large angle during the column selection in the small angle tilted state, effects row selection when tilted to the large angle once again, effects row determination when subsequently returned to the center position, and effects input of a Japanese kana letter by combining the determined column and row.

39. (Previously presented) The method of claim 38, wherein the direction designation unit inputs a consonant of the Japanese kana letter set at the time of the column input, and inputs a vowel of the Japanese kana letter set at the time of the row input.

40. (Previously presented) The method of claim 38, wherein the direction designation unit inputs letters in a romaji alphabet letter set at the time of the column input, and inputs the orders of the inputted letters at the time of the row input.

41. (Previously presented) The method of claim 27, which further comprises a button or like switch for switching a letter input operation and a cursor operation of the direction designation unit over to each other.

42. (Previously presented) The method of claim 41, wherein the direction designation can be switched to set up a cursor movement mode and a display scroll mode in dependence on angles of tilting it when used for the cursor operation, the cursor movement mode being set up by tilting the unit by small angle, the display scroll mode being set up by tilting the unit by a large angle.

43. (Previously presented) The method of claim 42, wherein when the direction designation unit is used for the cursor operation, the extent of movement of cursor is changed according to the tilting angle of the pointer for inputting commands concerning the display operation.

44. (Previously presented) The method of claim 38 wherein the direction designation unit includes an elastic member to let a tilting angle of the pointer be known with a feel of click.

45. (Previously presented) The method of claim 44, wherein the direction designation unit has a structure that the user is given a feel of click whenever the pointer being circumferentially moved reaches a direction designation position.

46. (Previously presented) A Japanese letter input method for inputting letters and symbols in a letter set for use in a Japanese letter input device, comprising the steps of

disposing predetermined letters and symbols in a concentric circle form; and

inputting letters or symbols by designating, in a predetermined sequence, coordinates on the concentric circle form corresponding to the letters and symbols by using a position input device, wherein selection of letters or symbols is made using a memory unit, and wherein the

letter set is a 50-letter set in which kana letters of the same consonant are arranged in a same direction, kana letters of the same vowel are arranged on a same circumference, and symbols are disposed in a directional concentric form.

47. (Previously presented) The Japanese letter input method of claim 46 wherein the symbols include the p-sound symbol.
